## Jean-Pierre Serre

Let $k$ be a field. Let $\operatorname{Cr}(k)$ be the Cremona group of rank 2 over $k$, i.e. the group of $k$-automorphisms of $k(X, Y)$, where $X$ and $Y$ are two indeterminates.

We shall be interested in the finite subgroups of $\operatorname{Cr}(k)$ of order prime to the characteristic of $k$. The case $k=\mathbf{C}$ has a long history, going back to the 19 -th century (see the references in [Bl 06] and [DI 07]), and culminating in an essentially complete (but rather complicated) classification, see [DI 07]. For an arbitrary field, it seems reasonable to simplify the problem à la Minkowski, as was done in [Se 07] for semisimple groups; this means giving a sharp multiplicative bound for the orders of the finite subgroups we are considering.

In $\S 6.9$ of [Se 07], I had asked a few questions in that direction, for instance the following :

If $k=\mathbf{Q}$, is it true that $\mathrm{Cr}(k)$ does not contain any element of prime order $\geqslant 11$ ?

More generally, what are the prime numbers $\ell$, distinct from $\operatorname{char}(k)$, such that $\operatorname{Cr}(k)$ contains an element of order $\ell$ ?

This question has now been solved by Dolgachev and Iskovskikh ([DI 08]), the answer being that there is equivalence between :
$\operatorname{Cr}(k)$ contains an element of order $\ell$
and
[ $\left.k\left(z_{\ell}\right): k\right]=1,2,3,4$ or 6 , where $z_{\ell}$ is a primitive $\ell$-th root of unity.
As we shall see, a similar method can handle arbitrary $\ell$-groups and one obtains an explicit value for the Minkowski bound of $\operatorname{Cr}(k)$, in terms of the size of the Galois group of the cyclotomic extensions of $k$ (cf. Th.2.1 below). For instance :

Theorem - Assume $k$ is finitely generated over its prime subfield. Then the finite subgroups of $\operatorname{Cr}(k)$ of order prime to char $(k)$ have bounded order. Let $M(k)$ be the least common multiple of their orders.
a) If $k=\mathbf{Q}$, we have $M(k)=120960=2^{7} \cdot 3^{3} .5 .7$.
b) If $k$ is finite with $q$ elements, we have: $M(k)= \begin{cases}3 .\left(q^{4}-1\right)\left(q^{6}-1\right) & \text { if } q \equiv 4 \text { or } 7(\bmod 9) \\ \left(q^{4}-1\right)\left(q^{6}-1\right) & \text { otherwise } .\end{cases}$

For more general statements, see $\S 2$. These statements involve the cyclotomic invariants of $k$ introduced in [Se 07, §6]; their definition is recalled in $\S 1$. The proofs are given in $\S 3$ (existence of large subgroups) and in $\S 4$ (upper bounds). For the upper bounds, we use a method introduced by Manin ([Ma 66]) and perfected by Iskovskikh ([Is 79], [Is 96]) and Dolgachev-Iskovskikh ([DI 08]) ; it
allows us to realize any finite subgroup of $\operatorname{Cr}(k)$ as a subgroup of $\operatorname{Aut}(S)$, where $S$ is either a del Pezzo surface or a conic bundle over a conic. A few conjugacy results are given in $\S 5$. The last $\S$ contains a series of open questions on the Cremona groups of rank $>2$.

## $\S 1$ The cyclotomic invariants $t$ and $m$

In what follows, $k$ is a field, $k_{s}$ is a separable closure of $k$ and $\bar{k}$ is the algebraic closure of $k_{s}$.

Let $\ell$ a prime number distinct from $\operatorname{char}(k)$; the $\ell$-adic valuation of $\mathbf{Q}$ is denoted by $v_{\ell}$. If $A$ is a finite set, with cardinal $|A|$, we write $v_{\ell}(A)$ instead of $v_{\ell}(|A|)$.

There are two invariants $t=t(k, l)$ and $m=m(k, l)$ which are associated with the pair $(k, l)$, cf. [Se 07, §4]. Recall their definitions :

### 1.1 Definition of $t$

Let $z \in k_{s}$ be a primitive $\ell$-th root of unity if $l>2$ and a primitive 4 -th root of unity if $\ell=2$. We put

$$
t=[k(z): k]
$$

If $\ell>2, t$ divides $\ell-1$. If $\ell=2$ or 3 , then $t=1$ or 2 .

### 1.2 Definition of $m$

For $\ell>2, m$ is the upper bound (possibly infinite) of the $n$ 's such that $k(z)$ contains the $\ell^{n}$-th roots of unity. We have $m \geqslant 1$.

For $\ell=2, m$ is the upper bound (possibly infinite) of the $n$ 's such that $k$ contains $z(n)+z(n)^{-1}$, where $z(n)$ is a primitive $2^{n}$-root of unity. We have $m \geqslant 2$. [The definition of $m$ given in [Se 07, §4.2] looks different, but it is equivalent to the one here.]
Remark. Knowing $t$ and $m$ amounts to knowing the image of the $\ell$-th cyclotomic character $\operatorname{Gal}\left(k_{s} / k\right) \rightarrow \mathbf{Z}_{l}^{*}$, cf. [Se 07, §4].

### 1.3 Example : $k=\mathbf{Q}$

Here, $t$ takes its largest possible value, namely $t=\ell-1$ for $\ell>2$ and $t=2$ for $\ell=2$. And $m$ takes its smallest possible value, namely $m=1$ for $\ell>2$ and $m=2$ for $\ell=2$.

### 1.4 Example : $k$ finite with $q$ elements

If $\ell>2$, one has :
$t=$ order of $q$ in the multiplicative group $\mathbf{F}_{\ell}^{*}$
$m=v_{\ell}\left(q^{t}-1\right)=v_{\ell}\left(q^{l-1}-1\right)$.

If $\ell=2$, one has :
$t=$ order of $q$ in $(\mathbf{Z} / 4 \mathbf{Z})^{*}$
$m=v_{2}\left(q^{2}-1\right)-1$.

## §2 Statement of the main theorem

Let $K=k(X, Y)$, where $X, Y$ are indeterminates, and let $\operatorname{Cr}(k)$ be the Cremona group of rank 2 over $k$, i.e. the group Aut $_{k} K$. Let $\ell$ be a prime number, distinct from $\operatorname{char}(k)$, and let $t$ and $m$ be the cyclotomic invariants defined above.

### 2.1 Notation

Define a number $M(k, \ell) \in\{0,1,2, \ldots, \infty\}$ as follows :
For $\ell=2, \quad M(k, \ell)=2 m+3$.
For $\ell=3, \quad M(k, \ell)= \begin{cases}4 & \text { if } t=m=1 \\ 2 m+1 & \text { otherwise. }\end{cases}$
For $\ell>3, \quad M(k, \ell)=\left\{\begin{array}{lll}2 m & \text { if } t=1 & \text { or } 2 \\ m & \text { if } t=3,4 & \text { or } 6 \\ 0 & \text { if } t=5 & \text { or } t>6 .\end{array}\right.$

### 2.2 The main theorem

Theorem 2.1.(i) Let $A$ be a finite subgroup of $\mathrm{Cr}(k)$. Then $v_{\ell}(A) \leqslant M(k, \ell)$.
(ii) Conversely, if $n$ is any integer $\geqslant 0$ which is $\leqslant M(k, \ell)$ then $\operatorname{Cr}(k)$ contains a subgroup of order $\ell^{n}$.
(In other words, $M(k, \ell)$ is the upper bound of the $v_{\ell}(A)$.)
The special case where $A$ is cyclic of order $\ell$ gives :
Corollary 2.2 ([DI 08]). The following properties are equivalent:
a) $\operatorname{Cr}(k)$ contains an element of order $\ell$
b) $\varphi(t) \leq 2$, i.e. $t=1,2,3,4$ or 6 .

Indeed, b$)$ is equivalent to $M(k, \ell)>0$.

### 2.3 Small fields

Let us say that $k$ is small if it has the following properties :
(2.3.1) $m(k, \ell)<\infty$ for every $\ell \neq \operatorname{char}(k)$
(2.3.2) $\quad t(k, \ell) \rightarrow \infty$ when $\ell \rightarrow \infty$.

Proposition 2.3. A field which is finitely generated over $\mathbf{Q}$ or $\mathbf{F}_{p}$ is small.
Proof. The formulae given in $\S 1.3$ and $\S 1.4$ show that both $\mathbf{F}_{p}$ and $\mathbf{Q}$ are small. If $k^{\prime} / k$ is a finite extension, one has

$$
\left[k^{\prime}: k\right] \cdot t\left(k^{\prime}, \ell\right) \geqslant t(k, \ell) \text { and } m\left(k^{\prime}, \ell\right) \leqslant m(k, \ell)+\log _{\ell}\left(\left[k^{\prime}: k\right]\right)
$$

which shows that $k$ small $\Rightarrow k^{\prime}$ small. If $k^{\prime}$ is a regular extension of $k$, then

$$
t\left(k^{\prime}, \ell\right)=t(k, \ell) \quad \text { and } \quad m^{\prime}\left(k^{\prime}, \ell\right)=m(k, \ell)
$$

which also shows that $k$ small $\Rightarrow k^{\prime}$ small. The proposition follows.
Assume now that $k$ is small. We may then define an integer $M(k)$ by the following formula

$$
\begin{equation*}
M(k)=\prod_{\ell} \ell^{M(k, \ell)} \tag{2.3.3}
\end{equation*}
$$

where $\ell$ runs through the prime numbers distinct from $\operatorname{char}(k)$. The formula makes sense since $M(k, \ell)$ is finite for every $\ell$ and is 0 for every $\ell$ but a finite number. With this notation, Th. 2.1 can be reformulated as :

Theorem 2.4. If $k$ is small, then the finite subgroups of $\operatorname{Cr}(k)$ of order prime to $\operatorname{char}(k)$ have bounded order, and the l.c.m. of their orders is the integer $M(k)$ defined above.

Note that this applies in particular when $k$ is finitely generated over its prime subfield.

### 2.4 Example : the case $k=\mathbf{Q}$

By combining 1.3 and 2.1, one gets

$$
M(\mathbf{Q}, \ell)= \begin{cases}7 & \text { for } \quad \ell=2 \\ 3 & \text { for } \quad \ell=3 \\ 1 & \text { for } \quad \ell=5,7 \\ 0 & \text { for } \quad \ell>7\end{cases}
$$

This can be summed up by :
Theorem 2.5. $M(\mathbf{Q})=2^{7} .3^{3} .5 .7$.

### 2.5 Example : the case of a finite field

Theorem 2.6. If $k$ is a finite field with $q$ elements, we have

$$
M(k)= \begin{cases}3 \cdot\left(q^{4}-1\right)\left(q^{6}-1\right) & \text { if } q \equiv 4 \text { or } 7 \quad(\bmod 9) \\ \left(q^{4}-1\right)\left(q^{6}-1\right) & \text { otherwise } .\end{cases}
$$

Proof. Denote by $M^{\prime}(k, \ell)$ the $\ell$-adic valuation of the right side of the formulae above.

If $\ell$ is not equal to $3, M^{\prime}(k, \ell)$ is equal to

$$
v_{\ell}\left(q^{4}-1\right)+v_{\ell}\left(q^{6}-1\right)
$$

and we have to check that $M^{\prime}(k, \ell)$ is equal to $M(k, \ell)$.

Consider first the case $\ell=2$. It follows from the definition of $m$ that $v_{2}\left(q^{2}-1\right)=m+1$, and hence $v_{2}\left(q^{4}-1\right)=m+2$ and $v_{2}\left(q^{6}-1\right)=m+1$. This gives $M^{\prime}(k, \ell)=2 m+3=M(k, \ell)$.

If $\ell>3$, the invariant $t$ is the smallest integer $>0$ such that $q^{t}=1(\bmod l)$. If $t=5$ or $t>6$, this shows that $M^{\prime}(k, \ell)=0$.

If $t=3$ or $6, q^{4}-1$ is not divisible by $\ell$ and $q^{6}-1$ is divisible by $\ell$; moreover, one has $v_{\ell}\left(q^{6}-1\right)=m$. This gives $M^{\prime}(k, \ell)=m=M(k, \ell)$. Similarly, when $t=4$, the only factor divisible by $\ell$ is $q^{4}-1$ and its $\ell$-adic valuation is $m$. When $t=1$ or 2 , both factors are divisible by $\ell$ and their $\ell$-adic valuation is $m$.

The argument for $\ell=3$ is similar : we have

$$
v_{3}\left(q^{4}-1\right)=m \quad \text { and } \quad v_{3}\left(q^{6}-1\right)=m+1
$$

The congruence $q \equiv 4$ or $7(\bmod 9)$ means that $t=m=1$.
For instance :

$$
\begin{gathered}
M\left(\mathbf{F}_{2}\right)=3^{3} .5 .7 ; \quad M\left(\mathbf{F}_{3}\right)=2^{7} .5 .7 .13 ; \quad M\left(\mathbf{F}_{4}\right)=3^{4} .5^{2} .7 .13 .17 \\
M\left(\mathbf{F}_{5}\right)=2^{7} .3^{3} .7 .13 .31 ; \quad M\left(\mathbf{F}_{7}\right)=2^{9} .3^{4} .5^{2} .19 .43
\end{gathered}
$$

### 2.6 Example : the $p$-adic field $\mathrm{Q}_{p}$

For $\ell \neq p$, the $t, m$ invariants of $\mathbf{Q}_{p}$ are the same as those of $\mathbf{F}_{\ell}$, and for $\ell=p$ they are the same as those of $\mathbf{Q}$.

This shows that $\mathbf{Q}_{p}$ is "small", and a simple computation gives

$$
M\left(\mathbf{Q}_{p}\right)=c(p) \cdot\left(p^{4}-1\right)\left(p^{6}-1\right)
$$

with
$c(2)=2^{7} ; c(3)=3^{3} ; c(5)=5 ; c(7)=3.7 ;$
$c(p)=3$ if $p>7$ and $p \equiv 4$ or $7(\bmod 9)$;
$c(p)=1$ otherwise.
For instance :
$M\left(\mathbf{Q}_{2}\right)=2^{7} .3^{3} .5 .7 ; \quad M\left(\mathbf{Q}_{3}\right)=2^{7} .3^{3} .5 .7 .13 ; \quad M\left(\mathbf{Q}_{5}\right)=2^{7} .3^{3} .5 .7 .13 .31 ;$
$M\left(\mathbf{Q}_{7}\right)=2^{9} .3^{4} .5^{2} \cdot 7 \cdot 19.43 ; \quad M\left(\mathbf{Q}_{11}\right)=2^{7} .3^{3} .5^{2} \cdot 7 \cdot 19.37 .61$.

### 2.7 Remarks

1. The statement of Th.2.6 is reminiscent of the formula which gives the order of $G(k)$, where $G$ is a split semisimple group and $|k|=q$. In such a formula, the factors have the shape $\left(q^{d}-1\right)$, where $d$ is an invariant degree of the Weyl group, and the number of factors is equal to the rank of $G$. Here also the number of factors is equal to the rank of Cr , which is 2 . The exponents 4 and 6 are less easy to interpret. In the proofs below, they occur as the maximal orders of the torsion elements of the " Weyl group " of Cr , which is $\mathbf{G} \mathbf{L}_{2}(\mathbf{Z})$. See also §6.
2. Even though Th. 2.6 is a very special case of Th.2.1, it contains almost as much information as the general case. More precisely, we could deduce Th.2.1.(i)
[which is the hard part] from Th. 2.6 by the Minkowski method of reduction $(\bmod p)$ explained in $[\operatorname{Se} 07, \S 6.5]$.
3. In the opposite direction, if we know Th.2.1.(i) for fields of characteristic 0 (in the slightly more precise form given in $\S 4.1$ ), we can get it for fields of characteristic $p>0$ by lifting over the ring of Witt vectors ; this is possible : all the cohomological obstructions vanish.
4. For large fields, the invariant $m$ can be $\infty$. If $t$ is not $1,2,3,4$ or 6 , Cor.2.2 tells us that $\operatorname{Cr}(k)$ is $\ell$-torsion-free. But if $t$ is one of these five numbers, the above theorems tell us nothing. Still, as in [Se 07, §14, Th. 12 and Th.13] one can prove the following :
a) If $t=3,4$ or 6 , then $\operatorname{Cr}(k)$ contains a subgroup isomorphic to $\mathbf{Q}_{\ell} / \mathbf{Z}_{\ell}$ and does not contain $\mathbf{Q}_{\ell} / \mathbf{Z}_{\ell} \times \mathbf{Q}_{\ell} / \mathbf{Z}_{\ell}$.
b) If $t=1$ or 2 , then $\operatorname{Cr}(k)$ contains a subgroup isomorphic to $\mathbf{Q}_{\ell} / \mathbf{Z}_{\ell} \times \mathbf{Q}_{\ell} / \mathbf{Z}_{\ell}$ and does not contain a product of three copies of $\mathbf{Q}_{\ell} / \mathbf{Z}_{\ell}$.

## §3 Proof of Theorem 2.1.(ii)

We have to construct large $\ell$-subgroups of $\mathrm{Cr}(k)$. It turns out that we only need two constructions, one for the very special case $\ell=3, t=1, m=1$, and one for all the other cases.

### 3.1 The special case $\ell=3, t=1, m=1$

We need to construct a subgroup of $\operatorname{Cr}(k)$ of order $3^{4}$. To do so we use the Fermat cubic surface $S$ given by the homogeneous equation

$$
x^{3}+y^{3}+z^{3}+t^{3}=0
$$

It is a smooth surface, since $p \neq 3$. The fact that $t=1$ means that $k$ contains a primitive cubic root of unity. This implies that the 27 lines of $S$ are defined over $k$, and hence $S$ is $k$-rational : its function field is isomorphic to $K=k(X, Y)$. Let $A$ be the group of automorphisms of $S$ generated by the two elements

$$
(x, y, z, t) \mapsto(r x, y, z, t) \quad \text { and } \quad(x, y, z, t) \mapsto(y, z, x, t)
$$

where $r$ is a primitive 3 -rd root of unity.
We have $|A|=3^{4}$ and $A$ is a subgroup of $\operatorname{Aut}(S)$, hence a subgroup of $\operatorname{Cr}(k)$.

### 3.2 The generic case

Here is the general construction :
One starts with a 2 -dimensional torus $T$ over $k$, with an $\ell$-group $C$ acting faithfully on it. Let $B$ be an $\ell$-subgroup of $T(k)$. Assume that $B$ is stable under $C$, and let $A$ be the semi-direct product $A=B . C$. If we make $B$ act on the variety $T$ by translations, we get an action of $A$, which is faithful. This gives an embedding of $A$ in $\operatorname{Aut}(k(T))$, where $k(T)$ is the function field of $T$. By a
theorem of Voskresinskii (see [Vo 98, §4.9]) $k(T)$ is isomorphic to $K=k(X, Y)$. We thus get an embedding of $A$ in $\operatorname{Cr}(k)$. Note that $B$ is toral, i.e. is contained in the $k$-rational points of a maximal torus of Cr .

It remains to explain how to choose $T, B$ and $C$. We shall define $T$ by giving the action of $\Gamma_{k}=\operatorname{Gal}\left(k_{s} / k\right)$ on its character group ; this amounts to giving an homomorphism $\Gamma_{k} \rightarrow \mathbf{G L} \mathbf{L}_{2}(\mathbf{Z})$.

### 3.2.1 The case $\ell=2$

Let $n$ be an integer $\leqslant m$. If $z(n)$ is a primitive $2^{n}$-root of unity, $k$ contains $z(n)+z(n)^{-1}$. The field extension $k(z(n)) / k$ has degree 1 or 2 , hence defines a character $\Gamma_{k} \rightarrow 1,-1$. Let $T_{1}$ be the 1-dimensional torus associated with this character. If $k(z(n))=k, T_{1}$ is the split torus $\mathbf{G}_{m}$ and we have $T_{1}(k)=k^{*}$. If $k(z(n))$ is quadratic over $k, T_{1}(k)$ is the subgroup of $k(z(n))^{*}$ made up of the elements of norm 1 . In both cases, $T_{1}(k)$ contains $z(n)$. We now take for $T$ the torus $T_{1} \times T_{1}$ and for $B$ the subgroup of elements of $T$ of order dividing $2^{n}$. We have $v_{2}(B)=2 n$. We take for $C$ the group of automorphisms generated by $(x, y) \mapsto\left(x^{-1}, y\right)$ and $(x, y) \mapsto(y, x)$; the group $C$ is isomorphic to the dihedral group $D_{4}$; its order is 8 . We then have $v_{2}(A)=v_{2}(B)+v_{2}(C)=2 n+3$, as wanted.
(Alternate construction : the group $\mathrm{Cr}_{1}(k)=\mathbf{P G L}_{2}(k)$ contains a dihedral subgroup $D$ of order $2^{n+1}$; by using the natural embedding of $\left(\mathrm{Cr}_{1}(k) \times \mathrm{Cr}_{1}(k)\right) .2$ in $\operatorname{Cr}(k)$ we obtain a subgroup of $\operatorname{Cr}(k)$ isomorphic to $(D \times D) .2$, hence of order $2^{2 n+3}$.)

### 3.2.2 The case $\ell>2$

We start similarly with an integer $n \leqslant m$. We may assume that the invariant $t$ is equal to $1,2,3,4$ or 6 ; if not we could take $A=1$. Call $C_{t}$ the Galois group of $k(z) / k$, cf. $\S 1$. It is a cyclic group of order $t$. Choose an embedding of $C_{t}$ in $\mathbf{G} \mathbf{L}_{2}(\mathbf{Z})$, with the condition that, if $t=2$, then the image of $C_{t}$ is $\{1,-1\}$. The composition map

$$
r: \Gamma_{k} \rightarrow \operatorname{Gal}(k(z) / k)=C_{t} \rightarrow \mathbf{G L}_{2}(\mathbf{Z})
$$

defines a 2-dimensional torus $T$.
The group $B$ is the subgroup $T(k)\left[l^{n}\right]$ of $T(k)$ made up of elements of order dividing $l^{n}$. We take $C$ equal to 1 , except when $l=3$ where we choose it of order 3 (this is possible since $t=1$ or 2 for $\ell=3$, and the group of $k$-automorphisms of $T$ is isomorphic to $\mathbf{G} \mathbf{L}_{2}(\mathbf{Z})$ ). We thus have :
$v_{\ell}(A)=v_{\ell}(B)$ if $\ell>3$ and $v_{\ell}(A)=1+v_{\ell}(B)$ if $\ell=3$.
It remains to estimate $v_{\ell}(B)$. Namely :
(3.2.3) $v_{\ell}(B)=2 n$ if $t=1$ or 2

This is clear if $t=1$ because in that case $T$ is a split torus of dimension 2 , and $k$ contains $z(n)$.

If $t=2$, then $T=T_{1} \times T_{1}$, where $T_{1}$ is associated with the quadratic character $\Gamma_{k} \rightarrow \operatorname{Gal}(k(z) / k)$. We may identify $T_{1}(k)$ with the elements of norm 1 of $k(z)$, and this shows that $z(n)$ is an element of $T_{1}(k)$ of order $2^{n}$. We thus get $v_{\ell}(B)=2 n$.
(3.2.4) $v_{\ell}(|B|) \geqslant n$ if $t=3,4$ or 6

We use the description of $T$ given in [Se 07, $\S 5.3$ ] : let $L$ be the field $k(z)$. It is a cyclic extension of $k$ of degree $t$. Let $s$ be a generator of $C_{t}=\operatorname{Gal}(L / k)$. Let $T_{L}=R_{L / k}\left(\mathbf{G}_{m}\right)$ be the torus ' multiplicative group of $L$ "; we have $\operatorname{dim} T_{L}=t$, and $s$ acts on $T_{L}$. We have $s^{t}-1=0$ in $\operatorname{End}\left(T_{L}\right)$. Let $F(X)$ be the cyclotomic polynomial of index $t$, i.e.

$$
\begin{array}{ll}
F(X)=X^{2}+X+1 & \text { if } t=3 \\
F(X)=X^{2}+1 & \text { if } t=4 \\
F(X)=X^{2}-X+1 & \text { if } t=6
\end{array}
$$

This polynomial divides $X^{t}-1$; let $G(X)$ be the quotient $\left(X^{t}-1\right) / F(X)$, and let u be the endomorphism of $T_{1}$ defined by $u=G(s)$. One checks (loc.cit.) that the image $T$ of $u: T_{1} \rightarrow T_{1}$ is a 2-dimensional torus, and $s$ defines an automorphism $s_{T}$ of $T$ of order $t$, satisfying the equation $F\left(s_{T}\right)=0$. This shows that $T$ is the same as the torus also called $T$ above. Moreover, it is easy to check that the element $z(n)$ of $T_{1}(k)$ is sent by $u$ into an element of $T(k)$ of order $l^{n}$ . This shows that $v_{\ell}(B) \geqslant n$.
[When $t=3$, we could have defined $T$ as the kernel of the norm map $N: T_{1} \rightarrow \mathbf{G}_{m}$. There is a similar definition for $t=4$, but the case $t=6$ is less easy to describe concretely.]

This concludes the proof of the "existence part" of Th.2.1.

## §4 Proof of Theorem 2.1.(i)

### 4.1 Generalization

In Th.2.1.(i), the hypothesis made on the $\ell$-group $A$ is that it is contained in $\operatorname{Cr}(k)$. This is equivalent to saying that $A$ is contained in $\operatorname{Aut}(S)$, where $S$ is a $k$-rational surface, cf. e.g. [DI 07,Lemma 6]. We now want to relax this hypothesis : we will merely assume that $S$ is a surface which is " geometrically rational ", i.e. becomes rational over $\bar{k}$; for instance $S$ can be any smooth cubic surface in $\mathbf{P}_{3}$. In other words, we will be interested in field extensions $L$ of $k$ with the property :
(4.1.1) $\quad \bar{k} \otimes L$ is $\bar{k}$-isomorphic to $\bar{k}(X, Y)$.

We shall say that a group $A$ has " property $\mathrm{Cr}_{k}$ " if it can be embedded in Aut $(L)$, for some $L$ having property (4.1.1). The bound given in Th.2.1.(i) is valid for such groups. More precisely :

Theorem 4.1. If a finite $\ell$-group $A$ has property $\operatorname{Cr}_{k}$, then $v_{\ell}(A) \leqslant M(k, \ell)$, where $M(k, \ell)$ is as in §2.1.

This is what we shall prove. Note that we may assume that $k$ is perfect since replacing $k$ by its perfect closure does not change the invariants $t, m$ and $M(k, l)$.
[As mentioned in $\S 2.7$, we could also assume that $k$ is finite, or, if we preferred to, that $\operatorname{char}(k)=0$. Unfortunately, none of these reductions is really helpful.]

### 4.2 Reduction to special cases

We start from an $\ell$-group $A$ having property $\mathrm{Cr}_{k}$. As explained above, this means that we can embed $A$ in $\operatorname{Aut}(S)$, where $S$ is a smooth projective $k$ surface, which is geometrically rational. Now, the basic tool is the " minimal model theorem " (proved in [DI 07, §2]) which allows us to assume that $S$ is of one of the following two types :
a) (conic bundle case) There is a morphism $f: S \rightarrow C$, where $C$ is a smooth genus zero curve, such that the generic fiber of $f$ is a smooth curve of genus 0 . Moreover, $A$ acts on $C$ and $f$ is compatible with that action.
b) (del Pezzo) $S$ is a del Pezzo surface, i.e. its anticanonical class $-K_{S}$ is ample.

In case b), the degree $\operatorname{deg}(S)$ is defined as $K_{S} \cdot K_{S}$ (self-intersection); one has $1 \leqslant \operatorname{deg}(S) \leqslant 9$.

We shall look successively at these different cases. In the second case, we shall use without further reference the standard properties of the del Pezzo surfaces; one can find them for instance in [De 80], [Do 07], [DI 07], [Ko 96], [Ma 66] and [Ma 86].

Remark. In some of these references, the ground field is assumed to be of characteristic 0 , but there is very little difference in characteristic $p>0$; moreover, as pointed out above, the characteristic 0 case implies the characteristic $p$ case, thanks to the fact that $|A|$ is prime to $\operatorname{char}(k)$.

### 4.3 The conic bundle case

Let $f: S \rightarrow C$ be as in a) above, and let $A_{o}$ be the subgroup of $\operatorname{Aut}(C)$ given by the action of $A$ on $C$. The group $\operatorname{Aut}(C)$ is a $k$-form of $\mathbf{P G L} \mathbf{L}_{2}$. By using (for instance) [Se 07, Th.5] we get :

$$
v_{\ell}\left(A_{o}\right) \leqslant\left\{\begin{array}{ll}
m+1 & \text { if } \quad l=2 \\
m & \text { if } \\
0 & \text { if } \quad t>2
\end{array} \text { and } t=1 \text { or } 2\right.
$$

Let $B$ be the kernel of $A \rightarrow A_{o}$. The group $B$ is a subgroup of the group of automorphisms of the generic fiber of $f$. This fiber is a genus 0 curve over the function field $k_{C}$ of $C$. Since $k_{C}$ is a regular extension of $k$, the $t$ and $m$ invariants of $k_{C}$ are the same as those of $k$. We then get for $v_{\ell}(B)$ the same bounds as for $v_{\ell}\left(A_{o}\right)$, and by adding up this gives :

$$
v_{\ell}(A) \leqslant \begin{cases}2 m+2 & \text { if } \quad \ell=2 \\ 2 m & \text { if } \quad \ell>2 \\ 0 & \text { if } \quad t>2\end{cases}
$$

In each case, this gives a bound which is at most equal to the number $M(k, \ell)$ defined in $\S 2.1$.

### 4.4 The del Pezzo case : degree 9

Here $S$ is $\bar{k}$-isomorphic to the projective plane $\mathbf{P}_{2}$; in other words, $S$ is a Severi-Brauer variety of dimension 2 . The group Aut $S$ is an inner $k$-form of $\mathbf{P G L}_{3}$. By using [Se 07, §6.2] one finds :

$$
v_{\ell}(A) \leqslant\left\{\begin{array}{lll}
2 m+1 & \text { if } & \ell=2 \\
2 m+1 & \text { if } & \ell=3, t=1 \\
\leq m+1 & \text { if } & \ell=3, t=2 \\
\leq 2 m & \text { if } & \ell>3, t=1 \\
\leq m & \text { if } & \ell>3, t=2 \text { or } 3 \\
=0 & \text { if } & t>3
\end{array}\right.
$$

Here again, these bounds are $\leqslant M(k, \ell)$.

### 4.5 The del Pezzo case : degree 8

This case splits into two subcases:
a) $S$ is the blow up of $\mathbf{P}_{2}$ at one rational point. In that case $A$ acts faithfully on $\mathbf{P}_{2}$ and we apply 4.4.
b) $S$ is a smooth quadric of $\mathbf{P}_{3}$. The connected component $\operatorname{Aut}{ }^{\circ}(S)$ of $\operatorname{Aut}(S)$ has index 2 . It is a $k$-form of $\mathbf{P G L} \mathbf{L}_{2} \times \mathbf{P G L}_{2}$. If we denote by $A_{o}$ the intersection of $A$ with $\operatorname{Aut}^{\circ}(S)$, we obtain, by [Se 07, Th.5], the bounds :

$$
v_{\ell}\left(A_{0}\right) \leqslant \begin{cases}2 m+2 & \text { if } \ell=2 \\ 2 m & \text { if } \ell>2 \text { and } t=1 \text { or } 2 \\ m & \text { if } t=3,4 \text { or } 6 \\ 0 & \text { if } t=5 \text { or } t>6\end{cases}
$$

Since $v_{\ell}(A)=v_{\ell}\left(A_{o}\right)$ if $\ell>2$ and $v_{\ell}(A) \leqslant v_{\ell}\left(A_{o}\right)+1$ if $\ell=2$, we obtain a bound for $v_{\ell}(A)$ which is $\leqslant M(k, \ell)$.

Remarks. 1) Note the case $\ell=2$, where the $M(k, \ell)$ bound $2 m+3$ can be attained.
2) In the case $t=6$, the bound $v_{\ell}\left(A_{o}\right) \leqslant m$ given above can be replaced by $v_{\ell}\left(A_{o}\right)=0$, but this is not important for what we are doing here.

### 4.6 The del Pezzo case : degree 7

This is a trivial case; there are 3 exceptional curves on $S$ (over $\bar{k}$ ), and only one of them meets the other two. It is thus stable under $A$, and by blowing it down, one is reduced to the degree 8 case. [This case does not occur if one insists, as in [DI 08], that the rank of $\operatorname{Pic}(S)^{A}$ be equal to 1.]

### 4.7 The del Pezzo case : degree 6

Here the surface $S$ has 6 exceptional curves (over $\bar{k}$ ), and the corresponding graph $L$ is an hexagon. There is a natural homomorphism

$$
g: \operatorname{Aut}(S) \rightarrow \operatorname{Aut}(L)
$$

and its kernel $T$ is a 2-dimensional torus. Put $A_{o}=A \cap T(k)$. The index of $A_{o}$ in $A$ is a divisor of 12 . By [Se 07, Th.4], we have

$$
v_{\ell}\left(A_{o}\right) \leqslant\left\{\begin{array}{lll}
2 m & \text { if } t=1 \text { or } 2 & \text { (i.e. if } \varphi(t)=1) \\
m & \text { if } t=3,4 \text { or } 6 \\
0 & \text { if } t=5 \text { or } t>6 . & \text { (i.e. if } \varphi(t)=2) \\
\end{array}\right.
$$

Hence :

$$
v_{\ell}(A) \leqslant \begin{cases}2 m+2 & \text { if } \ell=2 \\ 2 m+1 & \text { if } \ell=3 \\ 2 m & \text { if } \ell>3 \text { and } t=1 \text { or } 2 \\ m & \text { if } t=3,4 \text { or } 6 \\ 0 & \text { if } t=5 \text { or } t>6\end{cases}
$$

These bounds are $\leqslant M(k, \ell)$.
Remarks. 1) Note the case $t=6$, where the bound $m$ can actually be attained.
2) In the case $t=4$, the bound $v_{\ell}(A) \leqslant m$ given above can be replaced by $v_{\ell}(A)=0$.

### 4.8 The del Pezzo case : degree 5

As above, let $L$ be the graph of the exceptional curves of $S$. Since $\operatorname{deg}(S) \leqslant 5$, the natural map $\operatorname{Aut}(S) \rightarrow \operatorname{Aut}(L)$ is injective. We can thus identify $A$ with its image $A_{L}$ in $\operatorname{Aut}(L)$. In the case $\operatorname{deg}(S)=5$, $\operatorname{Aut}(L)$ is isomorphic to the symmetric group $S_{5}$. In particular we have

$$
v_{\ell}(A) \leqslant\left\{\begin{array}{lll}
3 & \text { if } & \ell=2 \\
1 & \text { if } \quad \ell=3 \text { or } 5 \\
0 & \text { if } \quad \ell>5
\end{array}\right.
$$

and we conclude as before.

### 4.9 The del Pezzo case : degree 4

This case is similar to the preceding one. Here $\operatorname{Aut}(L)$ is isomorphic to the group $2^{4} . S_{5}=\operatorname{Weyl}\left(D_{5}\right)$; its order is $2^{7} .3 .5$. We get the same bounds as above, except for $\ell=2$ where we find $v_{\ell}(A) \leqslant 7$, which is $\leqslant M(k, 2)$ [recall that $M(k, 2)=2 m+3$ and that $m \geqslant 2$ for $\ell=2$ ].

### 4.10 The del Pezzo case : degree 3

Here $S$ is a smooth cubic surface, and $A$ embeds in $\operatorname{Weyl}\left(E_{6}\right)$, a group of order $2^{7} .3^{4} .5$. This gives a bound for $v_{\ell}(A)$ which gives what we want, except when $\ell=3$. In the case $\ell=3$, it gives $v_{\ell}(A) \leqslant 4$, but Th.2.1 claims $v_{\ell}(A) \leqslant 3$ unless $k$ contains a primitive cubic root of unity. We thus have to prove the following lemma :

Lemma 4.2 - Assume that $|A|=3^{4}$, that $A$ acts faithfully on a smooth cubic surface $S$ over $k$, and that $\operatorname{char}(k) \neq 3$. Then $k$ contains a primitive cubic root of unity.

Proof. The structure of $A$ is known since $A$ is isomorphic to a 3-Sylow subgroup of $\operatorname{Weyl}\left(E_{6}\right)$. In particular the center $Z(A)$ of $A$ is cyclic of order 3 and is contained in the commutator group de $A$. Since $A$ acts on $S$, it acts on the sections of the anticanonical sheaf of $S$; we get in this way a faithful linear representation $r: A \rightarrow \mathbf{G L}_{4}(k)$. Over $\bar{k}, r$ splits as $r=r_{1}+r_{3}$ where $r_{1}$ is 1 dimensional and $r_{3}$ is irreducible and 3 -dimensional. If $z$ is a non trivial element of $Z(A)$, the eigenvalues of $z$ are $\{1, r, r, r\}$ where $r$ is a primitive third root of unity. This shows that $r$ belongs to $k$.

### 4.11 The del Pezzo case : degree 2

Here $A$ embeds in $\operatorname{Weyl}\left(E_{7}\right)$, a group of order $2^{10} .3^{4} .5 .7$. This gives a bound for $v(A)$, but this bound is not good enough. However, the surface $S$ is a 2 sheeted covering of $\mathbf{P}_{2}$ (the map $S \rightarrow \mathbf{P}_{2}$ being the anticanonical map) and we get a homomorphism $g: A \rightarrow \mathbf{P G L}_{3}(k)$ whose kernel has order 1 or 2 . We then find the same bounds for $v_{\ell}(A)$ as in $\S 4.2$, except that, for $\ell=2$, the bound is $2 m+2$ instead of $2 m+1$.

### 4.12 The del Pezzo case : degree 1

We use the linear series $\left|-2 K_{S}\right|$. It gives a map $g: S \rightarrow \mathbf{P}_{3}$ whose image is a quadratic cone $Q$, cf. e.g. [De 80, p.68]. This realizes $S$ as a quadratic covering of $Q$. If $B$ denotes the automorphism group of $Q$ defined by $A$, we have $v_{\ell}(A)=v_{\ell}(B)$ if $\ell>2$ and $v_{\ell}(A) \leqslant v_{\ell}(B)+1$ if $\ell=2$. But $B$ is isomorphic to a subgroup of $k^{*} \times \operatorname{Aut}(C)$, where $C$ is a curve of genus 0 . This implies

$$
v_{\ell}(B) \leqslant\left\{\begin{array}{lll}
m+m+1 & \text { if } \quad \ell=2 \\
m+m & \text { if } & t=1 \\
0+m & \text { if } \quad t=2, l>2 \\
0+0 & \text { if } \quad t>2
\end{array}\right.
$$

The corresponding bound for $v_{\ell}(A)$ is $\leqslant M(k, \ell)$.
This concludes the proof of Th.4.1 and hence of Th.2.1.

## §5 Structure and conjugacy properties of $\ell$-subgroups of $\operatorname{Cr}(k)$

### 5.1 The $\ell$-subgroups of $\mathrm{Cr}(k)$

The main theorem (Th.2.1) only gives information on the order of an $\ell$ subgroup $A$ of $\operatorname{Cr}(k)$, assuming as usual that $\ell \neq \operatorname{char}(k)$. As for the structure of $A$, we have :
Theorem 5.1. (i) If $\ell>3, A$ is abelian of rank $\leqslant 2$ (i.e. can be generated by two elements).
(ii). If $\ell=3$ (resp. $\ell=2$ ) A contains an abelian normal subgroup of rank $\leqslant 2$ with index $\leqslant 3$ (resp. with index $\leqslant 8$ ).

Proof. Most of this is a consequence of the results of [DI 07] ; see also [Bl 06] and $[\mathrm{Be} 07]$. The only case which does not seem to be explicitly in [DI 07] is the case $\ell=2$, when $A$ is contained in $\operatorname{Aut}(S)$, where $S$ is a conic bundle. Suppose we are in that case and let $f: S \rightarrow C$ and $A_{o}, B$ be as in 4.3, so that we have an exact sequence $1 \rightarrow B \rightarrow A \rightarrow A_{o} \rightarrow 1$, with $A_{o} \subset \operatorname{Aut}(C)$, and $B \subset \operatorname{Aut}(F)$ where $F$ is the generic fiber of $f$ (which is a genus zero curve over the function field $k(C)$ of $C)$. We use the following lemma :

Lemma 5.2. Let $a \in A$ and $b \in B$ be such that a normalizes the cyclic group $\langle b\rangle$ generated $b y b$. Then $a b a^{-1}$ is equal to $b$ or to $b^{-1}$.

Proof of the lemma. Let $n$ be the order of $b$. If $n=1$ or 2 , there is nothing to prove. Assume $n>2$. By extending scalars, we may also assume that $k$ contains the primitive $n$-th roots of unity. Since $b$ is an automorphism of $F$ of order $n$, it fixes two rational points of $F$ which one can distinguish by the eigenvalue of $b$ on their tangent space : one of them gives a primitive $n$-th root of unity $z$, and the other one gives $z^{\prime}=z^{-1}$. [Equivalently, $b$ fixes two sections of $f: S \rightarrow C$.] The pair $\left(z, z^{\prime}\right)$ is canonically associated with $b$. Hence the pair associated with $a b a^{-1}$ is also $\left(z, z^{\prime}\right)$. On the other hand, if $a b a^{-1}=b^{i}$ with $i \in \mathbf{Z} / n \mathbf{Z}$, then the pair associated to $a^{i}$ is $\left(z^{i}, z^{\prime i}\right)$. This shows that $z^{i}$ is equal to either $z$ or $z^{-1}$, hence $i \equiv 1$ or $-1(\bmod n)$. The result follows.

End of the proof of Theorem 5.1 in the case $\ell=2$. Since $B$ is a finite 2-subgroup of a $k(C)$-form of $\mathbf{P G L}_{2}$, it is either cyclic or dihedral. In both cases, it contains a characteristic subgroup $B_{1}$ of index 1 or 2 which is cyclic. Similarly, $A$ has a cyclic subgroup $A_{1}$ which is of index 1 or 2 . Let $a \in A$ be such that its image in $A_{o}$ generates $A_{1}$. If $b$ is a generator of $B_{1}$, Lemma 5.2 shows that $a^{2}$ commutes with $b$. Let $\left\langle b, a^{2}\right\rangle$ be the abelian subgroup of $A$ generated by $b$ and $a^{2}$. It is normal in $A$, and the inclusions $\left\langle b, a^{2}\right\rangle \subset\langle b, a\rangle \subset B .\langle a\rangle \subset A$ show that its index in $A$ is at most 8 .

Remark. Similar arguments can be applied to prove a Jordan-style result on the finite subgroups of $\operatorname{Cr}(k)$, namely :

Theorem 5.3. There exists an integer $J>1$, independent of the field $k$, such that every finite subgroup $G$ of $\operatorname{Cr}(k)$, of order prime to char $(k)$, contains an abelian normal subgroup $A$ of rank $\leqslant 2$, whose index in $G$ divides $J$.

The proof follows the same pattern : the conic bundle case is handled via Lemma 5.2 and the del Pezzo case via the fact that $G$ has a subgroup of bounded index which is contained in a reductive group of rank $\leqslant 2$, so that one can apply the usual form of Jordan's theorem to that group. As for the value of $J$, a crude computation shows that one can take $J=2^{10} .3^{4} .5^{2} .7$; the exponents of 2 and 3 can be somewhat lowered, but those of 5 and 7 cannot since $\mathrm{Cr}(\mathbf{C})$ contains $A_{5} \times A_{5}$ and $\mathbf{P S L}_{2}\left(\mathbf{F}_{7}\right)$.

### 5.2 The cases $\mathbf{t}=3,4,6$

More precise results on the structure of $A$ depend on the value of the invariant $t=t(k, \ell)$. Recall that $t=1,2,3,4$ or 6 if $A \neq 1$, cf. Cor.2.2. We shall only consider the cases $t=3,4$ or 6 which are the easiest. See [DI 08, §4] for a (more difficult) conjugation theorem which applies when $t=1$ or 2. Recall (cf. $\S 3.2)$ that $A$ is said to be toral if there exists a 2 -dimensional subtorus $T$ of Cr (in the sense of [De 70]) such that $A$ is contained in $T(k)$. We have :
Theorem 5.4. Assume that $t=3,4$ or 6 . Then :
(a) $A$ is cyclic of order $\ell^{n}$ with $n \leqslant m$.
(b) $A$ is toral, except possibly if $|A|=5$.
(c) If $A^{\prime}$ is a subgroup of $\operatorname{Cr}(k)$ of the same order as $A$, then $A^{\prime}$ is conjugate to $A$ in $\operatorname{Cr}(k)$, except possibly if $|A|=5$.

Note that the hypothesis $t=3,4$ or 6 implies $\ell \geqslant 5$. Moreover, if $\ell=5$, then $t=4$ and, if $\ell=7$, then $t=3$ or 6 .

Proof of (a) and (b). We follow the same method as above, i.e. we view $A$ as a subgroup of $\operatorname{Aut}(S)$, where $S$ is either a conic bundle or a del Pezzo surface. The bounds given in $\S 4.3$ show that $A=1$ if $S$ is a conic bundle (this is why this case is easier than the case $t=1$ or 2 ). Hence we may assume that $S$ is a del Pezzo surface. Let $d$ be its degree. We have an exact sequence :

$$
1 \rightarrow G(k) \rightarrow \operatorname{Aut}(S) \rightarrow E \rightarrow 1
$$

where $G=\operatorname{Aut}(S)^{o}$ is a connected linear group of rank $\leqslant 2$ and $E$ is a subgroup of a Weyl group $W$ depending on $d$ (e.g. $W=\operatorname{Weyl}\left(E_{8}\right)$ if $d=1$ ).

Consider first the case $\ell>7$. The order of $W$ is not divisible by $\ell$; hence $A$ is contained in $G(k)$. Since $A$ is commutative, there exists a maximal torus $T$ of $G$ such that $A$ is contained in the normalizer $N$ of $T$, cf. e.g. [Se 07, §3.3]; since $\ell>3$, the order of $N / T$ is prime to $\ell$, hence $A$ is contained in $T(k)$ and this implies $\operatorname{dim}(T) \geqslant 2$ by [Se 07, $\S 4.1]$. This proves (b), and (a) follows from Lemma 5.5 below.

Suppose now that $\ell=5$ or 7 , and let $n=v_{\ell}(A)$. If $n=1$ and $\ell=5$, there is nothing to prove. If $n=1$ and $\ell=7$, then (a) is obvious and (b) is proved in [DI 08, prop.3] (indeed Dolgachev and Iskovskikh prove (b) when $v_{\ell}(A)=1$, and they also prove (c) for $\ell=7$ ). We may thus assume that $n>1$. If $d \leqslant 5$, then $G=1$ and $A$ embeds in $E$; but $E$ does not contain any subgroup of order $\ell^{2}$ (see the tables in [DI 07] and [Bl 06]) ; hence this case does not occur. If $d>5$, then the order of $E$ is prime to $\ell$, hence $A$ is contained in $G(k)$ and the proof above applies.

Proof of (c). By (b), we have $A \subset T(k)$ and $A^{\prime} \subset T^{\prime}(k)$ where $T$ and $T^{\prime}$ are 2dimensional subtori of Cr. By Lemma 5.5 below, these tori are isomorphic ; by a standard argument (see e.g. [De 70, $\S 6]$ this implies that $T$ and $T^{\prime}$ are conjugate by an element of $\operatorname{Cr}(k)$; moreover $A$ (resp. $A^{\prime}$ ) is the unique subgroup of order $\ell^{n}$ of $T(k)$ (resp. of $T^{\prime}(k)$ ). Hence $A$ and $A^{\prime}$ are conjugate in $\mathrm{Cr}(k)$.

Remark. The case $|A|=5$ is indeed exceptional : there are examples of such $A$ 's which are not toral, cf. [Be 07], [Bl 06], [DI 07].

### 5.3 A uniqueness result for 2-dimensional tori

We keep the assumption that $t=3,4$ or 6 . We have seen in $\S 3.2 .2$ that there exists a 2 -dimensional $k$-torus $T$ such that $T(k)$ contains an element of order $\ell$.

Lemma 5.5. (a) Such a torus is unique, up to $k$-isomorphism.
(b) If $n \leqslant m=m(k, \ell)$, then $T(k)\left[\ell^{n}\right]$ is cyclic of order $\ell^{n}$.

Proof of (a). Let $L=\operatorname{Hom}_{k_{s}}\left(\mathbf{G}_{m}, T\right)$ be the group of cocharacters of $T$. It is a free $\mathbf{Z}$-module of rank 2 , with an action of $\Gamma_{k}=\operatorname{Gal}\left(k_{s} / k\right)$. If we identify $L$ with $\mathbf{Z}^{2}$, this action gives a homomorphism $r: \Gamma_{k} \rightarrow \mathbf{G} \mathbf{L}_{2}(\mathbf{Z})$ which is well defined up to conjugation. Let $G$ be the image of $r$. Since $G$ is a finite subgroup of $\mathbf{G L}_{2}(\mathbf{Z})$, its order divides 24 , and hence is prime to $\ell$.

The $\Gamma_{k}$-module $T\left(k_{s}\right)[\ell]$ of the $\ell$-division points of $T\left(k_{s}\right)$ is canonically isomorphic to $L / \ell L \otimes \mu_{\ell}$, where $\mu_{\ell}$ is the group of $\ell$-th roots of unity in $k_{s}$. This means that $L / \ell L$ contains a rank- 1 submodule $I$ which is isomorphic to the dual $\mu_{\ell}^{*}$ of $\mu_{\ell}$. The action of $G$ on $L / \ell L$ is semisimple since $|G|$ is prime to $\ell$. Hence there exists a rank- 1 submodule $J$ of $L / \ell L$ such that $L / \ell L=I \bigoplus J$. By a well-known lemma of Minkowski (see e.g. [Se 07, Lemma 1]), the action of $G$ on $L / \ell L$ is faithful. This shows that $G$ is commutative. Moreover, the character giving the action of $\Gamma_{k}$ on $I$ has an image which is cyclic of order $t$. Since $t=3,4$
or 6 , this shows that $G$ contains an element of order 3 or 4 . One checks that these properties imply $G \subset \mathbf{S L}_{2}(\mathbf{Z})$ i.e. $\operatorname{det}(r)=1$, hence the $\Gamma_{k}$-modules $I$ and $J$ are dual of each other, i.e. $J \simeq \mu_{\ell}$. We thus have $L / \ell L \simeq \mu_{l} \oplus \mu_{\ell}^{*}$. We may then identify $r$ with the homomorphism $\Gamma_{k} \rightarrow C_{t} \rightarrow \mathbf{G L} 2(\mathbf{Z})$, where $C_{t}$ is the Galois group of $k\left(\mu_{\ell} / k\right)$ and $C_{t} \rightarrow \mathbf{G L}_{2}(\mathbf{Z})$ is an inclusion. Since any two such inclusions only differ by an inner automorphism of $\mathbf{G} \mathbf{L}_{2}(\mathbf{Z})$, this shows that the $\Gamma_{k}$-module $L$ is unique, up to isomorphism; hence the same is true for $T$. Proof of (b). Assertion (b) follows from the description of $T$ given in §3.2.2. It can also be checked by writing explicitly the $\Gamma_{k}$-module $L / \ell^{n} L$; when $n \leqslant m$ this module is isomorphic to the direct sum of $\mu_{\ell^{n}}$ and its dual.

## Remarks.

1). If $n>m$ we have $T(k)\left[\ell^{n}\right]=T(k)\left[\ell^{m}\right]$. This can be seen, either by a direct computation of $\ell$-adic representations, or by looking at $\S 3.2 .2$
2) When $t=1$ or 2 , it is natural to ask for a 2 -dimensional torus $T$ such that $T(k)$ contains $\mathbf{Z} / \ell Z \oplus \mathbf{Z} / \ell \mathbf{Z}$. Such a torus exists, as we have seen in §3.2. If $\ell>2$, it is unique, up to isomorphism. There is a similar result for $\ell=2$, if one asks not merely that $T(k)$ contains $\mathbf{Z} / 2 \mathbf{Z} \times \mathbf{Z} / 2 \mathbf{Z}$ but that it contains $\mathbf{Z} / 4 \mathbf{Z} \times \mathbf{Z} / 4 \mathbf{Z}$.

## §6 The Cremona groups of rank $>2$

For any $r>0$ the Cremona group $\mathrm{Cr}_{r}(k)$ of rank $r$ is defined as the group Aut $_{k} k\left(T_{1}, \ldots, T_{r}\right)$ where $\left(T_{1}, \ldots, T_{r}\right)$ are $r$ indeterminates. When $r>2$ not much seems to be known on the finite subgroups of $\mathrm{Cr}_{r}(k)$, even in the classical case $k=\mathbf{C}$. For instance :
6.0. Does there exist a finite group which is not embeddable in $\mathrm{Cr}_{3}(\mathbf{C})$ ?

This looks very likely, but I do not see how to prove it. Still, it is natural to ask for much more, e.g. :
6.1 (Jordan bound, cf. Th.5.5). Does there exist an integer $N(r)>0$, depending only on $r$, such that, for every finite subgroup $G$ of $\operatorname{Cr}_{r}(k)$ of order prime to $\operatorname{char}(k)$, there exists an abelian normal subgroup $A$ of $G$, of rank $\leqslant r$, whose index divides $N(r)$ ?

Note that this would imply that, for $\ell$ large enough (depending on $r$ ), every finite $\ell$-subgroup of $\mathrm{Cr}_{r}(k)$ is abelian of rank $\leqslant r$.
6.2 (cf. [Se 07, §6.9] ). Is it true that $r \geqslant \varphi(t)$ if $\mathrm{Cr}_{r}(k)$ contains an element of order $\ell$ ?
6.3. Let $G \subset \mathrm{Cr}_{r}(k)$ be as in 6.1, and assume that $k$ is small (cf. §2.3).Is it true that $|G|$ is bounded by a constant depending only on $r$ and $k$ ?

If the answer to 6.3 is " yes "we may define $M_{r}(k)$ as the l.c.m. of all such $|G|$ 's, and ask for an estimate of $M_{r}(k)$. For instance, in the case $r=3$ :
6.4. Is it true that $M_{3}(k)$ is equal to $M_{1}(k) . M_{2}(k)$ ?

If $k$ is finite with $q$ elements, this means (cf. $\S 2.5$ ) :
6.5. Is it true that

$$
M_{3}(k)= \begin{cases}3 \cdot\left(q^{2}-1\right)\left(q^{4}-1\right)\left(q^{6}-1\right) & \text { if } q \equiv 4 \text { or } 7(\bmod 9) \\ \left(q^{2}-1\right)\left(q^{4}-1\right)\left(q^{6}-1\right) & \text { otherwise } ?\end{cases}
$$

For larger $r$ 's the polynomial $\left(X^{2}-1\right)\left(X^{4}-1\right)\left(X^{6}-1\right)$ of 6.5 should be replaced by the polynomial $P_{r}(X)$ defined by the formula

$$
P_{r}(X)=\prod_{d} \Phi_{d}(X)^{[r / \varphi(d)]}
$$

where $\Phi_{d}(X)$ is the $d$-th cyclotomic polynomial $\left(\Phi_{1}(X)=X-1, \Phi_{2}(X)=\right.$ $\left.X+1, \Phi_{3}(X)=X^{2}+X+1, \Phi_{4}(X)=X^{2}+1, \ldots\right)$.
Examples. $P_{4}(X)=\left(X^{6}-1\right)\left(X^{8}-1\right)\left(X^{10}-1\right)\left(X^{12}-1\right) ; P_{5}(X)=\left(X^{2}-1\right) P_{4}(X)$.
With this notation, the natural question to ask seems to be :
6.6. Is it true that there exists an integer $c(r)>0$ such that $M_{r}\left(\mathbf{F}_{q}\right)$ divides $c(r) . P_{r}(q)$ for every $q$ ?

Unfortunately, I do not see any way to attack these questions; the method used for rank 2 is based on the very explicit knowledge of the "minimal models", and this is not available for higher ranks. Other methods are needed.

Acknowlegment. I wish to thank A.Beauville for a series of e-mails in 2003-2005 which helped me to correct the naive ideas I had on the Cremona group.
