Abstract

In this lecture we intend to study the finite subgroups of the group $\operatorname{Aut}_R R[[Z]]$ of *R*-automorphisms of the formal power series ring R[[Z]].

Notations

(K, v) is a discretely valued complete field of inequal characteristic (0, p). Typically a finite extension of \mathbb{Q}_p^{unr} .

R denotes its valuation ring.

 π is a uniformizing element and $v(\pi) = 1$.

 $k := R/\pi R$, the residue field, is algebraically closed of char. p > 0

 (K^{alg}, v) is a fixed algebraic closure endowed with the unique prolongation of the valuation *v*.

 ζ_p is a primitive *p*-th root of 1 and $\lambda = \zeta_p - 1$ is a uniformizing element of $\mathbb{Q}_p(\zeta_p)$.

Introduction

Let us cite J. Lubin (Non archimedean dynamical sytems. Compositio 94).

"Some of the standard and well-established techniques of local arithmetic geometry can also be seen as involving dynamical systems.

Let K/\mathbb{Q}_p be a finite extension. For a particular formal group F (the so called Lubin-Tate formal groups) we get a representation of $\text{Gal}(K^{alg}/K)$ from the torsion points of a particular formal group F over R the valuation ring of K. They occur as the roots of the iterates of $[p]_F(X) = pX + ...$, the endomorphism of multiplication by p.

They occur as well as the fix points of the automorphism (of formal group) given by $[1+p]_F(X) = F(X, [p]_F(X)) = (1+p)X + \dots$ "

In these lectures we focuss our attention on power series $f(Z) \in R[[Z]]$ such that $f(0) \in \pi R$ and $f^{\circ n}(Z) = Z$ for some n > 0. This is the same as considering cyclic subgroups of $\operatorname{Aut}_R R[[Z]]$. More generally we study finite order subgroups of the group $\operatorname{Aut}_R R[[Z]]$ throughout their occurence in "arithmetic geometry".

Generalities

The ring R[[Z]]

Definition

Distinguished polynomials. $P(Z) \in R[Z]$ is said to be distinguished if $P(Z) = Z^n + a_{n-1}Z^{n-1} + ... + a_0, a_i \in \pi R$

Theorem

Weierstrass preparation theorem. Let $f(Z) = \sum_{i \ge 0} a_i Z^i \in R[[Z]]$ $a_i \in \pi R$ for $0 \le i \le n-1$. $a_n \in R^{\times}$. The integer n is the Weierstrass degree for f. Then f(Z) = P(Z)U(Z) where $U(Z) \in R[[Z]]^{\times}$ and P(Z) is distinguished of degree n are uniquely defined.

Lemma

Division lemma. $f, g \in R[[Z]] f(Z) = \sum_{i \ge 0} a_i Z^i \in R[[Z]] a_i \in \pi R$ for $0 \le i \le n-1$. $a_n \in R^{\times}$ There is a unique $(q, r) \in R[[Z]] \times R[Z]$ with g = qf + r.

Open disc

Let $X := \operatorname{Spec} R[[Z]].$

Closed fiber $X_s := X \times_R k = \operatorname{Spec} k[[Z]]$: two points generic point (π) and closed point (π, Z)

Generic fiber $X_K := X \times_R K = \operatorname{Spec} R[[Z]] \otimes_R K$. Note that $R[[Z]] \otimes_R K = \{\sum_i a_i Z^i \in K[[Z]] \mid \inf_i v(a_i) > -\infty\}.$

generic point (0) and closed points (P(Z)) where P(Z) is an irreducible distinguished polynomial.

$$\begin{split} X_{(K^{alg})} &\simeq \{ z \in K^{alg} \mid v(z) > 0 \} \text{ is the open disc in } K^{alg} \text{ so that we can identify} \\ X_K &= R[[Z]] \otimes_R K \text{ with } \frac{X_{(K^{alg})}}{\operatorname{Gal}(K^{alg}/K)}. \end{split}$$

Although $X = \operatorname{Spec} R[[Z]]$ is a minimal regular model for X_K we call it the open disc over K.

$\operatorname{Aut}_{R}R[[Z]]$

Let $\sigma \in \operatorname{Aut}_{R}R[[Z]]$ then

- σ is continuous for the (π, Z) topology.
- $(\pi, Z) = (\pi, \sigma(Z))$
- $R[[Z]] = R[[\sigma(Z)]]$
- Reciprocally if $Z' \in R[[Z]]$ and $(\pi, Z) = (\pi, Z')$ i.e. $Z' \in \pi R + ZR[[Z]]^{\times}$, then $\sigma(Z) = Z'$ defines an element $\sigma \in \operatorname{Aut}_R R[[Z]]$
- σ induces a bijection $\tilde{\sigma} : \pi R \to \pi R$ where $\tilde{\sigma}(z) := (\sigma(Z))_{Z=z}$
- $\tau \tilde{\sigma}(z) = \tilde{\sigma}(\tilde{\tau}(z)).$

・ 同 ト ・ ヨ ト ・ ヨ ト

Structure theorem

Let $r: R[[Z]] \to R/(\pi)[[z]]$, be the canonical homomorphism induced by the reduction mod π .

It induces a surjective homomorphism $r : \operatorname{Aut}_R R[[Z]] \to \operatorname{Aut}_k k[[Z]]$. $N := \ker r = \{ \sigma \in \operatorname{Aut}_R R[[Z]] \mid \sigma(Z) = Z \mod \pi \}.$

Proposition

Let $G \subset \operatorname{Aut}_R R[[Z]]$ be a subgroup with $|G| < \infty$, then G contains a unique p-Sylow subgroup G_p and C a cyclic subgroup of order prime to p with $G = G_p \rtimes C$. Moreover there is a parameter Z' of the open disc such that $C = < \sigma >$ where $\sigma(Z') = \zeta_p Z'$.

< ロ > < 同 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ >

The proof uses several elementary lemmas

Lemma

- Let $e \in \mathbb{N}^{\times}$ and $f(Z) \in \operatorname{Aut}_{R} R[[Z]]$ of order e and $f(Z) = Z \mod Z^{2}$ and then e = 1.
- Let $f(Z) = a_0 + a_1Z + ... \in R[[Z]]$ with $a_0 \in \pi R$ and for some $e \in \mathbb{N} * let$ $f^{\circ e}(Z) = b_0 + b_1Z + ..., then \ b_0 = a_0(1 + a_1 + ... + a_1^{e-1}) \mod a_0^2 R$ and $b_1 = a_1^e \mod a_0 R$.
- Let $\sigma \in \operatorname{Aut}_{R} R[[Z]]$ with $\sigma^{e} = Id$ and (e,p) = 1 then σ has a rational fix point.
- Let σ as above then σ is linearizable.

向下 イヨト イヨト

Proof

The case |G| = e is prime to p.

Claim. $G = \langle \sigma \rangle$ and there is Z' a parameter of the open disc such that $\sigma(Z') = \theta Z'$ for θ a primitive *e*-th root of 1.In other words σ is linearizable.

 $N \cap G = \{1\}$. By item 4, $\sigma \in G$ is linearisable and so for some parameter Z' one can write $\sigma(Z') = \theta Z'$ and if $\sigma \in N$ we have $\sigma(Z) = Z \mod \pi R$, and as (e,p) = 1 it follows that $\sigma = Id$.

The homomorphism $\varphi: G \to k^{\times}$ with $\varphi(\sigma) = \frac{r(\sigma)(z)}{z}$ is injective (apply item 1 to the ring R = k). The result follows.

イロト 不得 とくき とくき とうき

General case.

From the first part it follows that $N \cap G$ is a *p*-group.

Let $\overline{G} := r(G)$. This is a finite group in $\operatorname{Aut}_k k[[z]]$.

Let
$$\overline{G}_1 := \ker(\varphi : \overline{G} \to k^{\times})$$
 given by $\varphi(\sigma) = \frac{\sigma(z)}{z}$

this is the *p*-Sylow subgroup of \overline{G} .

In particular $\frac{\overline{G}}{\overline{G_1}}$ is cyclic of order *e* prime to *p*.

Let $G_p := r^{-1}(\overline{G}_1)$, this is the unique *p*-Sylow subgroup of *G* as $N \cap G$ is a *p*-group.

Now we have an exact sequence $1 \to G_p \to G \to \frac{\overline{G}}{\overline{G}_1} \simeq \mathbb{Z}/e\mathbb{Z} \to 1$. The result follows by Hall's theorem.

Remark.

Let G be any finite p-group.

There is a dvr, *R* which is finite over \mathbb{Z}_p and an injective morphism $G \to \operatorname{Aut}_R R[\![Z]\!]$ which induces a free action of *G* on $\operatorname{Spec} R[\![Z]\!] \times K$ and which is the identity modulo π .

In particular the extension of dvr $R[[Z]]_{(\pi)}/R[[Z]]^G_{(\pi)}$ is fiercely ramified.

くぼう くほう くほう

The local lifting problem

Let G be a finite p-group. The group G occurs as an automorphism group of k[[z]] in many ways.

This is a consequence of the Witt-Shafarevich theorem on the structure of the Galois group of a field K of characteristic p > 0.

This theorem asserts that the Galois group $I_p(K)$ of its maximal *p*-extension is pro-*p* free on $|K/\mathcal{O}(K)|$ elements (as usual \mathcal{O} is the operator Frobenius minus identity).

We apply this theorem to the power series field K = k((t)). Then $K/\mathcal{O}(K)$ is infinite so we can realize *G* in infinitely many ways as a quotient of I_p and so as Galois group of a Galois extension L/K.

The local field *L* can be uniformized: namely L = k((z)). If $\sigma \in G = \text{Gal}(L/K)$, then σ is an isometry of (L, v) and so *G* is a group of *k*-automorphisms of k[[z]] with fixed ring $k[[z]]^G = k[[t]]$.

Definition

The local lifting problem for a finite *p*-group action $G \subset \operatorname{Aut}_k k[[z]]$ is to find a dvr, *R* finite over W(k) and a commutative diagram

$$\begin{array}{rcl} \operatorname{Aut}_k \llbracket \llbracket Z \rrbracket & \leftarrow & \operatorname{Aut}_R R \llbracket Z \rrbracket \\ \uparrow & \nearrow \\ G \end{array}$$

A *p*-group *G* has the local lifting property if the local lifting problem for all actions $G \subset \operatorname{Aut}_k k[[z]]$ has a positive answer.

Inverse Galois local lifting problem for *p*-groups

Let *G* be a finite *p*-group, we have seen that *G* occurs as a group of *k*-automorphism of k[[z]] in many ways,

so we can consider a weaker problem than the local lifting problem.

Definition

For a finite *p*-group *G* we say that *G* has the inverse Galois local lifting property if there exists a dvr, *R* finite over W(k), a faithful action $i: G \to \operatorname{Aut}_k k[[z]]$ and a commutative diagram

$$\begin{array}{rcl} \operatorname{Aut}_k k[\![z]\!] & \leftarrow & \operatorname{Aut}_R R[\![Z]\!] \\ i \uparrow & \nearrow \\ G \end{array}$$

・ 同 ト ・ ヨ ト ・ ヨ

Sen's theorem

Sen's theorem

Let $G_1(k) := zk[[z]]$ endowed with composition law. We write v for v_z . The following theorem was conjectured by Grothendieck.

Theorem

Sen (1969). Let $f \in G_1(k)$ such that $f^{\circ p^n} \neq Id$. Let $i(n) := v(f^{\circ p^n}(z) - z)$, then $i(n) = i(n-1) \mod p^n$.

Sketch proof (Lubin 95). The proof is interesting for us because it counts the fix points for the iterates of a power series which lifts f.

Let
$$X^{alg} := \{ z \in K^{alg} \mid v(z) > 0 \}$$

Let $F(Z) \in R[[Z]]$ such that

• F(0) = 0 and $F^{\circ p^n}(Z) \neq Z \mod \pi R$

• The roots of $F^{\circ p^n}(Z) - Z$ in X^{alg} are simple.

Then $\forall m$ such that $0 < m \le n$ one has $i(m) = i(m-1) \mod p^m$ where $i(n) := v(\tilde{F}^{\circ p^n}(z) - z)$ is the Weierstrass degree of $F^{\circ p^n}(z) - Z$.

16/33

Proof:

Claim: let
$$Q_m(Z) := \frac{F^{\circ p^n}(Z) - Z}{F^{\circ p^{n-1}}(Z) - Z} \in R[[Z]]$$

For this we remark that if $F^{\circ p^{m-1}}(Z) - Z = (Z - z_0)^a V(Z)$ with a > 1 and $z_0 \in X^{alg}$, then $F^{\circ p^m}(Z) - Z = (Z - z_0)^a W(Z)$ i.e. the multiplicity of fix points increases in particular the roots of $F^{\circ p^{m-1}}(Z) - Z$ are simple as those of $F^{\circ p^n}(Z) - Z$.

It follows that the series $Q_i(Z)$ for $1 \le i \le n$ have distinct roots.

Let z_0 with $Q_m(z_0) = 0$ then $z_0, F(z_0), \dots, F^{\circ p^m - 1}(z_0)$ are distinct roots of $Q_m(Z)$.

・ロト ・ 同ト ・ ヨト ・ ヨト ・ ヨ

Sen's theorem

Reversely if $|\{z_0, F(z_0), ..., F^{\circ p^m - 1}(z_0)\}| = p^m$ and if $F^{\circ p^m}(z_0) = z_0$, then z_0 is a root of $Q_m(Z)$.

In other words z_0 is a root of $Q_m(Z)$ iff $|\operatorname{Orb} z_0| = p^m$.

It follows that the Weierstrass degree i(m) - i(m-1) of $Q_m(Z)$ is $0 \mod p^m$. Now Sen's theorem follows from the following

Lemma

k be an algebraically closed field of char. p > 0 $f \in k[[z]]$ with $f(z) = z \mod (z^2)$, and n > 0 such that $f^{\circ p^n}(z) \neq z$. There is a complete dvr R with char. R > 0 and $R/(\pi) = k$ and $F(Z) \in R[[Z]]$ with r(F) = f such that $F^{\circ p^n}(Z) - Z$ has simple roots in X^{alg} .

< ロ > < 同 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ >

Hasse-Arf theorem

Notations.

 O_K is a complete dvr with $K = \operatorname{Fr} O_K$.

L/K is a finite Galois extension with group G.

 O_L is the integral closure of O_K .

 π_K, π_L uniformizing elements, k_K, k_L the residue fields

The residual extension k_L/k_K is assumed to be separable.

There is a filtration $(G_i)_{i\geq -1}$ with $G_i := \{\sigma \in G \mid v_L(\sigma(\pi_L) - \pi_L) \geq i+1\}$ $G = G_{-1} \supset G_0 \supset G_1...$ $G_i \triangleleft G$

 $G/G_0 \simeq \operatorname{Gal}(k_L/k_K)$

 G/G_1 is cyclic with order prime to char. k_K

If char. $k_K = 0$ the group G_1 is trivial

If char. $k_K = p$ the group G_1 is a *p*-group.

 G_i/G_{i+1} is a *p* elementary abelian group.

The different ideal $\mathscr{D}_{L/K} \subset O_L$.

Under our hypothesis there is $z \in O_L$ such that $O_L = O_K[z]$, then $\mathscr{D}_{L/K} = (P'(z))$ where *P* is the irreducible polynomial of *z* over *K*. It follows that $v_L(\mathscr{D}_{L/K}) = \sum_{i \ge 0} (|G_i| - 1)$ **Period**

Ramification jumps

An integer $i \ge 1$ such that $G_i \ne G_{i+1}$ is a jump. Moreover if $G_t \ne G_{t+1} = 1$ then $i = t \mod p$.

Sen's theorem implies Hasse-Arf theorem for power series.

Theorem

Hasse-Arf. Let $i \ge 1$ *such that* $G_i \ne G_{i+1}$ *then* $\varphi(i) := \frac{1}{|G_0|} (\sum_{0 \le j \le i} |G_j|)$ *is an integer.*

Corollary

When G is a p-group which is abelian then for s < t are two consecutive jumps $G_s \neq G_{s+1} = ... = G_t \neq G_{t+1}$ one has $s = t \mod (G : G_t)$.

Proposition

Let $G \subset \operatorname{Aut}_k k[[z]]$ a finite group. Then $k[[z]]^G = k[[t]]$ and k((z))/k((t)) is Galois with group G.

Proof. This is a special case of the following theorem.

Theorem

Let A be an integral ring and $G \subset \operatorname{Aut}_A Z[[Z]]$ a finite subgroup then $A[[Z]]^G = A[[T]]$. Moreover $T := \prod_{g \in G} g(Z)$ works.

When A is a noetherian complete integral local ring the result is due to Samuel.

くぼう くほう くほう

The local lifting problem for $G \simeq \mathbb{Z}/p\mathbb{Z}$

Proposition

Let k be an algebraically closed of char. p > 0. Let $\sigma \in \operatorname{Aut}_k k[[z]]$ with order p. Then there is $m \in \mathbb{N}^{\times}$ prime to p such that $\sigma(z) = z(1+z^m)^{-1/m}$.

Proof: Artin-Schreier theory gives a parametrization for *p*-cyclic extensions in char. p > 0. There $f \in k((z))$ such that $\operatorname{Tr}_{k((z))/k((t))} f = 1$. Let $x := -\sum_{1 \le i \le p} i\sigma^i(f)$, then $\sigma(x) = x + 1$ and so $y := x^p - x \in k((t))$ and so k((z)) = k((t))[z] and $X^p - X - y$ is the irreducible polynomial of x over k((t)). We write $y = \sum_{i > i_0} a_i t^i$. By Hensel's lemma we can assume that $a_i = 0$ for $i \ge 0$. Now we remark that for i = pj we can write $a_i = b_i^p$ and that $a_{pi}/t^{pj} = b/t^j + (b/t^j)^p - b/t^j$ and finally we can assume that $y = (b/t^m)(1 + tP(t))$ for some $b \in k^*$ and $P(t) \in k[t]$ and (m, p) = 1. Then changing t by $t/(b(1+tP(t))^{1/m})$ we can assume that $f = 1/t^m$. An exercise shows that $z' := x^{-1/m} \in k((z))$ is a uniformizing parameter. As $\sigma(z') = (x+1)^{-1/m}$, the result follows. < ロ > < 同 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ >

Proposition

Let ζ_p be a primitive p-th root of 1 in K^{alg} and m > 0 and prime to p. Let $F(Z) := \zeta_p Z(1+Z^m)^{-1/m}$, it defines an order p automorphism $\Sigma \in \operatorname{Aut}_R R[[Z]]$ for $R = W(k)[\zeta_p]$ and $r(\Sigma(Z)) = \sigma(z)$. In other words Σ is a lifting of σ .

Proof: $\Sigma(Z^m) = \zeta_p^m \frac{Z^m}{1+Z^m}$ is an homographical transformation on Z^m of order p. So $\Sigma^p(Z) = \theta Z$ with $\theta^m = 1$.

Now we remark that $\Sigma(Z) = \zeta_p(Z) \mod Z^2$ and so $\Sigma^p(Z) = Z \mod Z^2$. ///

The geometry of fix points.

Fix $\Sigma = \{z \in X^{alg} \mid z = \zeta_p z (1+z^m)^{-1/m}\}$ then Fix $\Sigma = \{0\} \cup \{\theta_m^i (\zeta_p^m - 1)^{1/m}\}, \ 1 \le i \le m, \ \theta_m$ is a primitive *m*-th root of 1.

The mutual distances are all equal ; this is the equidistant geometry.

Geometric method.

We can mimic at the level of *R*-algebras what we have done for *k*-algebras. Namely one can deform the isogeny $x \to x^p - x$ in $X \to \frac{(\lambda X+1)^p - 1}{\lambda^p}$.

So we can lift over *R* any dvr finite over $W(k)[\zeta_p]$ at the level of fields $x^p - x = 1/t^m$ in (*) $\frac{(\lambda X+1)^p - 1}{\lambda^p} = \frac{1}{\prod_{1 \le i \le m} (T-t_i)}$ with $t_i \in X^{alg}$

(*) defines a *p*-cyclic cover of \mathbb{P}^1_K which is highly singular.

Take the normalisation of \mathbb{P}^1_R , we get generically a *p*-cyclic cover C_η of \mathbb{P}^1_K whose branch locus *Br* is given by the roots of

$$(\prod_{1 \le i \le m} (T - t_i))(\lambda^p + \prod_{1 \le i \le m} (T - t_i))$$
 with prime to p multiplicity.

・ロト ・ 同ト ・ ヨト ・ ヨト ・ ヨ

We would like a smooth *R*-curve.

We calculate the genus.

$$2(g(C_{\eta}) - 1) = 2p(0 - 1) + |Br|(p - 1) + m(p - 1)$$

The special fiber C_s is reduced and geometric genus $2(g(C_s)-1) = 2p(0-1) + (m+1)(p-1)$

and it is smooth iff |Br|(p-1) + m(p-1) = (m+1)(p-1).

This is the case when the t_i are all equal. For example for $(**) \quad \frac{(\lambda X+1)^p-1}{\lambda p} = \frac{1}{Tm}$

When we consider the cover between the completion of the local rings at the closed point (π, T) we recover the order p automorphism $\in \operatorname{Aut}_R R[[Z]]$ considered above.

p^n -cyclic groups

Oort conjecture.

There is a conjecture named in the litterature "Oort conjecture" which states that the local lifting problem for the group $\mathbb{Z}/p^n\mathbb{Z}$ as a positive answer.

The conjecture was set after global considerations relative to the case n = 1 which we have seen is elementary in the local case and so works in the global case due to a local-global principle.

It became serious when a proof along the lines of the geometric method described above was given in the case n = 2.

Recently a proof was announced by Obus and Wewers for the case n = 3 and for n > 3 under an extra condition (see the recent survey A. Obus: The (local) lifting problem for curves, arXiv 8 May 2011).

In the next paragraph we give a method using formal groups which gives a positive answer to the inverse Galois problem for cyclic p-groups.

We illustrate this method in the case n = 1.

イロン 不良 とくほう 不良 とうせい

p^n -cyclic groups and formal groups

Notations

K is a finite totally ramified extension of $\mathbb{Q}_p[\zeta_p]$ of degree *n*.

 $R := O_K$ and π a uniformising parameter.

 $f(Z) := \sum_{i \ge 0} \frac{Z^{p^k}}{\pi^k} \in K[[Z]]$ (the series exp(f(Z)) is the so-called Artin-Hasse exponential) $F(Z_1, Z_2) := f^{\circ -1}(f(Z_1) + f(Z_2)) \in K[[Z_1, Z_2]]$ $[\pi]_F(Z) := f^{\circ -1}(\pi f(Z)) \in K[[Z]].$ The main result is that $F(Z_1, Z_2) \in R[[Z_1, Z_2]]$ and $[\pi]_F(Z) \in R[[Z]]$. Moreover $[\pi]_F(Z) = \pi Z \mod Z^2$ and $[\pi]_F(Z) = Z^p \mod \pi$ It follows that for all $a \in R$ there is $[a]_F(Z) \in R[[Z]]$ such that $[a]_F(F(Z_1, Z_2)) = F([a]_F(Z_1), [a]_F(Z_2))$ and $[a]_F(Z) = aZ \mod Z^2$. Then $a \in R \to [a]_F(Z)$ is an injective homomorphism of R into End_F . For example $\sigma(Z) := [\zeta_p]_F(Z) = f^{\circ -1}(\zeta_p f(Z))$ is an order *p*-automorphism of R[Z] which is not trivial mod π and with p^n fix points whose geometry is well understood. ・ロト ・ 同ト ・ ヨト ・ ヨト ・ ヨ

Obstructions to the local lifting problem

There is a local version of the criterium of good reduction which involves degrees of differents.

Proposition

Let A = R[[T]) and B be a finite A-module and a normal integral local ring. Set $A_K := A \otimes_R K$ and $B_K := B \otimes_R K$, $A_0 := A/\pi A$ and $B_0 := B/\pi B$. We assume that B_0 is reduced and that B_0/A_0 is generically étale. Let B_0^{alg} the B_0 integral closure and $\delta_k(B) := \dim_k B_0^{alg}/B_0$. Let d_η resp. d_s the degree of the generic resp. special different. Then $d_\eta = d_s + 2\delta_k(B)$ and $d_\eta = d_s$ iff B = R[[Z]]. Application: the local lifting problem for $G = (\mathbb{Z}/p\mathbb{Z})^2$

The ramification filtration.

 $G = G_0 = G_1 = \ldots = G_{m_1} \supseteq G_{m_1+1} \supset \ldots \supset G_{m_2} \supseteq G_{m_2+1} = 0$ The extension is birationnaly defined by $k((z)) = k((t))[x_1, x_2]$ where $x_1^p - x_1 = 1/t^{m'_1}, x_2^p - x_2 = a_{m'_2}/t^{m'_2} + \dots + a_1/t$ where $m'_1 \leq m'_2$ are prime to $p, a_{m'_2} \in k^{\times}$ and $a_{m'_2} \notin \mathbb{F}_p$ if $m'_1 = m'_2$. One can show that $m_1 = m'_1$ and $m_2 = m'_2 p - m'_1 (p-1)$. Then $d_s = (m_1 + 1)(p^2 - 1) + (m_2 - m_1)(p - 1).$ Let R[[Z]]/R[[T]] be a lifting then $d_n = (m'_1 + 1 - d)p(p-1) + (m'_2 + 1 - d)p(p-1) + dp(p-1)$, where d is the number of branch points in common in the lifting of the two basis covers. A necessary and sufficient condition is that $d_s = d_n$ i.e. $dp = (m_1 + 1)(p - 1)$. In particular $m_1 = -1 \mod p$, this is an obstruction to the local lifting problem when p > 2.

The inverse local lifting problem for $G = (Z/pZ)^n$, n > 1

The condition $dp = (m_1 + 1)(p - 1)$ is not easy to realize because the geometry of branch points is rigid as we will see in the last lecture. Nevertheless one can show that the inverse Galois problem for $G = (Z/pZ)^n$ has a positive answer.

Here is a proof in the case p = 2 and n = 3. It depends on the following lemma

Lemma

$$p = 2, \text{ and let}$$

$$Y^{2} = f(X) = (1 + \alpha_{1}X)(1 + \alpha_{2}X)(1 + (\alpha_{1}^{1/2} + \alpha_{2}^{1/2})^{2}X)$$
with $\alpha_{i} \in W(k)^{alg}$ and let $a_{i} \in k$ the reduction of $\alpha_{i} \mod \pi$. We assume that $a_{1}a_{2}(a_{1} + a_{2})(a_{1}^{2} + a_{2}^{2} + a_{1}a_{2}) \neq 0$.
Then $f(X) = (1 + \beta X)^{2} + \alpha_{1}\alpha_{2}(\alpha_{1}^{1/2} + \alpha_{2}^{1/2})^{2}X^{3}$.
Set $R := W(k)[2^{1/3}]$ and $X = 2^{2/3}T^{-1}$, and $Y = 1 + \beta X + 2Z$
then $Z^{2} + (1 + 2^{2/3}\beta T)Z = \alpha_{1}\alpha_{2}(\alpha_{1}^{1/2} + \alpha_{2}^{1/2})^{2}T^{-3}$ which gives mod π
 $z^{2} + z = a_{1}a_{2}(a_{1} + a_{2})^{2}t^{-3}$.

The idea is to consider the compositum of three 2-cyclic covers of \mathbb{P}^1_K given by

$$\begin{aligned} Y_1^2 &= (1 + \alpha_1 X)(1 + \alpha_2 X)(1 + (\alpha_1^{1/2} + \alpha_2^{1/2})^2 X) \\ Y_1^2 &= (1 + \alpha_2 X)(1 + \alpha_3 X)(1 + (\alpha_2^{1/2} + \alpha_3^{1/2})^2 X) \\ Y_1^2 &= (1 + \alpha_3 X)(1 + \alpha_1 X)(1 + (\alpha_3^{1/2} + \alpha_1^{1/2})^2 X) \\ \text{with } a_1 + a_2 + a_3 \neq 0, \ 1 + (a_1 + a_2 + a_3)(a_1^{-1} + a_2^{-1} + a_3^{-1}) \neq 0 \text{ and} \\ \text{analoguous conditions as in the lemma.} \end{aligned}$$

Then any pair of 2-covers have in common 2 branch points and any triple of 2-covers have in common 1 branch point. This insure that $d_{\eta} = d_s$

Minimal stable model for the pointed disc

From now we shall assume that σ is an order *p*-automorphism and the its fix points are rational over *K*.

Proposition

Order p-automorphisms with one fix point are linearizable.

Now we assume that $|Fix \sigma| = m + 1 > 1$ and $Fix \sigma = \{z_0, z_1, ..., z_m\}$

Minimal stable model for the pointed disc $(X, \operatorname{Fix} \sigma)$

The method:

Let
$$v(\rho) = inf_{i \neq j} \{v(z_i - z_j)\} = v(z_{i_0} - z_{i_1})$$

A blowing up along the ideal $(Z - z_{i_0}, \rho)$ induces a new model in which the specialization map induces a non trivial partition on Fix σ .

An induction argument will produce a minimal stable model \mathscr{X}_{σ} for the pointed disc (*X*, Fix σ).

Michel Matignon (IMB)

Geometry of order p-automorphisms of the disc

Proposition

The fix points specialize in \mathscr{X}_{σ} in the terminal components.

Theorem

Let $\sigma \in \operatorname{Aut}_R R[[Z]]$ be an automorphism of order p such that $1 < |\operatorname{Fix} \sigma| = m + 1 < p$, $r(\sigma) \neq Id$. Then the minimal stable model for the pointed disc $(X, \operatorname{Fix} \sigma)$ has only one component.

There is a finite number of conjugacy classes of such automorphisms.
